TECH**

**Northeastern University**

# Selective vs. Adaptive Security

- **Selective security:**

- Adversary has to commit to some or all of its choices ahead of time
- Not very realistic
- Easier to get

- **Adaptive security:**

- Adversary can make various choices during the course of the attack
- More realistic
- Harder to get

# Recent Work & Our Results

Modular reduction  
to pebbling &  
guessing arguments

Several recent works showing that schemes actually **satisfy adaptive security**:

- Generalized selective decryption (GSD) [Panjwani07, FJP15]
- Constrained PRFs [FKPR14]
- Garbled circuits [JW16]

Very long and technical

Similar framework by  
Ananth et al [TCC 2016]

Vague consensus that proof  
techniques are related but no  
clear understanding

- A framework that connects these works and allows us to present them in a unified and simplified fashion
- New result for adaptive security of Yao's secret sharing scheme

# The Hybrid Argument & Random Guessing

- Let  $G_L$  and  $G_R$  be two adaptive game
- Let  $H_L$  and  $H_R$  be their *selectivized* versions where the adversary commits to  $w \in \{0,1\}^n$
- Assume that there is some sequence  $H_L = H_0, H_1, \dots, H_\ell = H_R$  such that we can show that  $H_i$  and  $H_{i+1}$  are indistinguishable.
- Then,  $G_L$  and  $G_R$  are indistinguishable with security loss  $2^n \ell$ .

# The Main Idea Underlying Our Framework

- Devise a sequence of hybrids such that to prove their indis. it is enough for the adversary to commit to  $h(w) \in \{0,1\}^m$ ,  $m \ll n$ 
  - May be a different  $h$  for every pair of hybrids
  - Across all hybrids we may need to know all of  $w$
- Security loss is  $2^m \ell \ll 2^n \ell$

# The GSD Problem [Panjwani07]

- Have many secret keys  $k_1, \dots, k_n$  and adversary can:
  - Ask for  $\text{Enc}(k_i, k_j)$  --- Encryption query
  - Ask to get  $k_i$  --- Corruption query
  - Make a challenge on key  $k_i$  --- Challenge
- Decide whether it's **real** or **random**
- Goal: distinguish between the two cases
  - No cycles
  - Key is **not** corrupted

Directly corrupted or is reachable from such

# The GSD Problem – Selective Security

- Graph and all queries are known ahead of time
- Design  $n^2$  hybrids where in each replace one honest encryption with a bogus one
  - Each pair is indistinguishable by IND-CPA
- Security loss is  $n^2$

What about adaptive security?

# The GSD Problem – Adaptive Security

- Can reduce to the selective case by guessing the graph ( $n^2$  bits)
- Security loss is  $n^2 \cdot 2^{n^2}$

Can prove adaptive security without losing so much?

## Known results:

- The graph is of depth  $d$ 
  - Loss is  $(2n)^d$  [Panjwani07]
- The graph is a tree
  - Loss is  $n^{3 \log n}$  [FJP15]
- The graph is a path
  - Loss is  $n^{\log n}$  [FJP15]

# GSD on a PATH

- There is a path of length  $n$  & some permutation  $\sigma$
- Adversaries queries are of the form  $\text{Enc}(\sigma(i - 1), \sigma(i))$
- The challenge is for  $k_{\sigma(n)}$
  
- Know the permutation  $\Rightarrow$  know all queries.
- Know the order in which we replace ciphertext with bogus ones.

# GSD on a PATH

- Any hybrid is defined by a path where some edges have black pebbles
- A pebble means that the corr. encryption query is replied with bogus

$$\text{Enc}(k_{\sigma(i)}, k_{\sigma(i+1)}) \Rightarrow \text{Enc}(k_{\sigma(i)}, r)$$

....

- Goal is to move from no pebble to the case that only the  $(n - 1, n)$  edge has a pebble
  - This is exactly the “random” game
- Pebbling rules:
  - Put/remove pebble on the source  $(0, 1)$  edge
  - Put/remove pebble on  $(i, i + 1)$  if  $(i - 1, i)$  has one.

# GSD on a PATH

- In the adaptive case we don't know the permutation.
  - Need to guess the edge where there's a pebble
- Unfortunately, # of pebbles is too large so guessing is too expensive

Goal: Find a pebbling strategy with not so many moves and as few as possible pebbles.

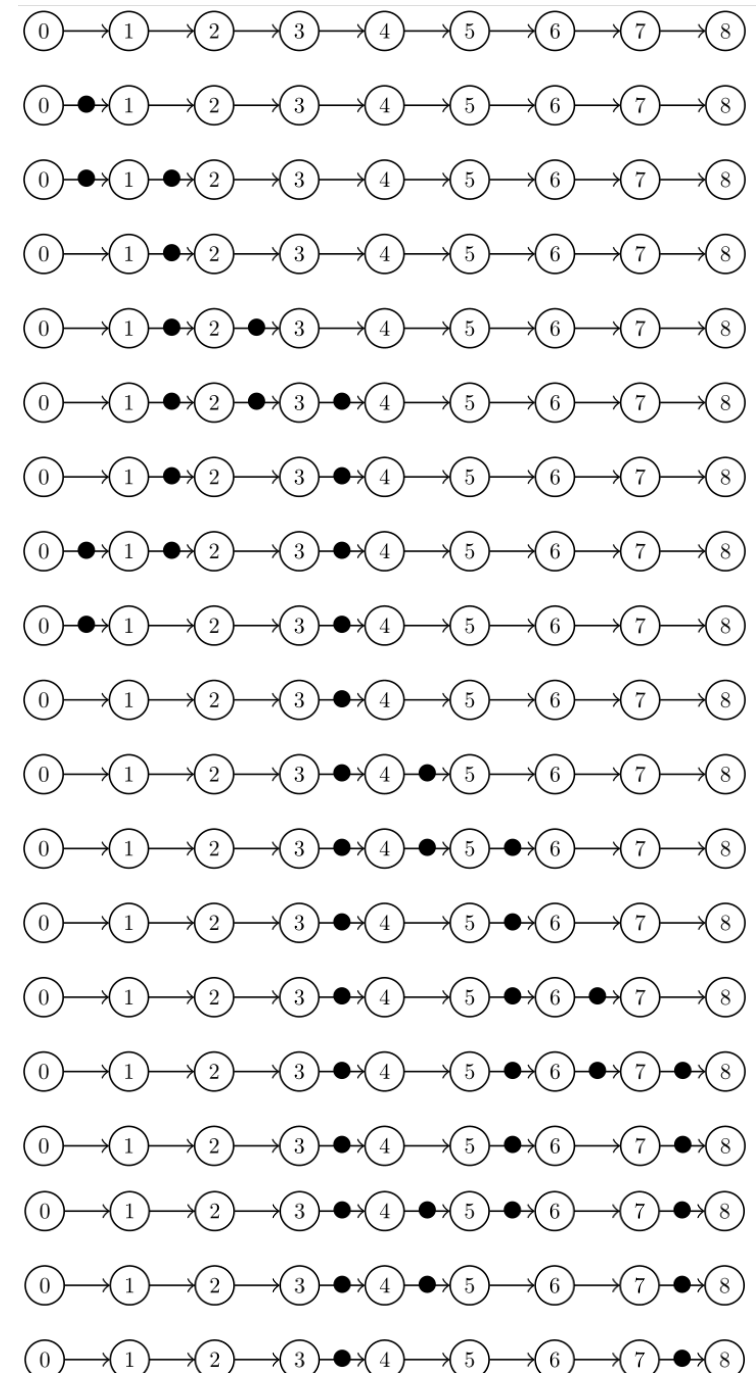

Loss will be  $\ell n^p$   
 $\ell$  - # of hybrids  
 $p$  - max # of pebbles

# GSD on a PATH

- Recursive pebbling:
  - Pebble the middle
  - Pebble the right-most vertex
  - Remove the middle pebble
- $\log n + 1$  pebbles &  $3^{\log n}$  moves

Loss is  $\approx n^{\log n} \cdot 3^{\log n}$

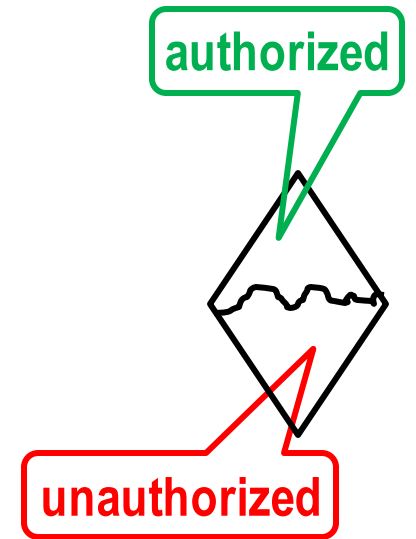

# Secret Sharing

- **Dealer** has a secret  $S$
- Gives to users shares  $\Pi_1, \dots, \Pi_n$ 
  - The shares are a probabilistic function of  $S$
- A subset of users  $X$  is either **qualified** or **unqualified**
- Authorized sets form a *monotone* access structure

## Goal:

- A **qualified**  $X$  can reconstruct  $S$  based on their shares.
- An **unqualified**  $X$  **cannot** gain *any* knowledge about  $S$ .

Perfect / Computational

$i \in [n]$

$\Pi_i$

Adv wins if

$S' = S$

# Our Result For Yao's Scheme

## Theorem [Adaptive Security Loss in Yao's Scheme]:

Given an access structure described by a Boolean circuit with **fanin**  $k_{\text{in}}$  and **fanout**  $k_{\text{out}}$  with  $s$  gates and **depth**  $d$ , the loss in Yao's scheme is

$$2^{d(\log s + \log k_{\text{in}})} \cdot (2k_{\text{in}})^{2d} \cdot k_{\text{out}} \\ \approx \\ s^{O(d)}$$

# Yao's Scheme

Assume fanin and fanout 2.

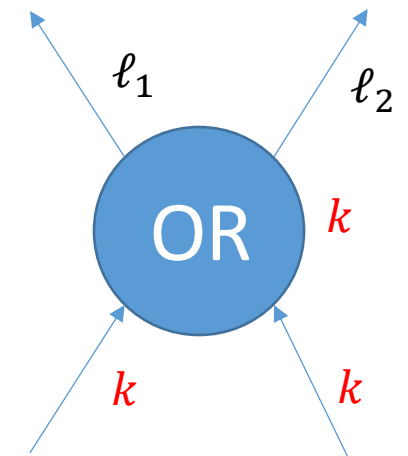

- Label the output wire with the secret
- Label all wires in the circuit from root to inputs
- The labels of the inputs are given to the corresponding parties

1. Sample SKE key  $k$
2. If **AND**:  
One-time pad  $k$
3. If **OR**:  
Duplicate  $k$
4. Encrypt the out labels under  $k$

Give each party:

$Enc_k(\ell_1)$   
 $Enc_k(\ell_2)$

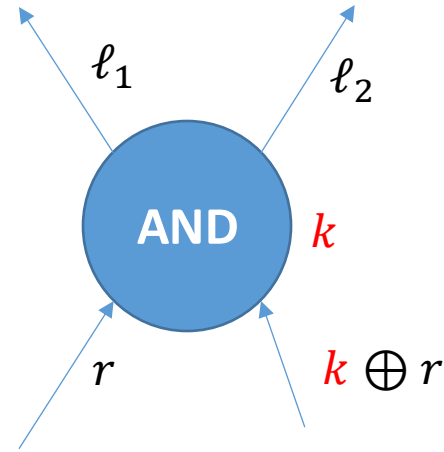

# Proof of Selective Security

Give each party:

$Enc_k(\ell_1)$

$Enc_k(\ell_2)$

- Via a sequence of hybrids.
- Slowly replace ciphertexts with **bogus** ones
- We can do this for every gate for which the **adv cannot compute the corresponding key**
- When we do this to output gate  $\Rightarrow$  **shares are indep. of secret**
- How do we know who are these gates?
- **Selective security:** adv commits to his set of parties ahead of time!

**Seems inherent to know the set in order to devise such a sequence**

- Such a sequence exists since chosen set is unqualified

# Proof of Adaptive Security

- Devise a new sequence of hybrids.
- Hybrid  $H_i$  corresponds to a *pebbling configuration* in which every gate is either pebbled or not.

- **Pebbled** gate  $\Leftrightarrow$  **bogus** ciphertext
- **Unpebbled** gate  $\Leftrightarrow$  **real** ciphertext

# Proof of Adaptive Security

- Hybrid  $H_i$  corresponds to a *pebbling configuration* in which every gate is either pebbled or not.
- From hybrid  $H_i$  to hybrid  $H_{i+1}$  via pebbling rules:
  - Place/remove a pebble on AND gate for which **at least one** input is connected to a pebbled gate
  - Place/remove a pebble on OR gate for which **all** inputs are connected to pebbled gates.

# Proof of Adaptive Security

Main idea:

- In order to move from  $H_i$  to  $H_{i+1}$ , no need to know the corrupted set, but only the *pebble configurations* in these two hybrids
- If, in addition, each pebbling configuration requires *few* bits to describe, we can guess it.

**Goal:** Find a pebbling strategy with not so many moves that can be **described** with few bits.

# Proof of Adaptive Security

We give a pebbling strategy that requires  $2^{O(d)}$  steps and each configuration can be described by  $d \cdot \log s$  bits.

Pebbling Configuration:

- Pairs of the form (GateName, Bit)
- Bit will say if only left child is pebbled or both
- Another bit to specify whether root is pebbled

# Proof of Adaptive Security

We give a pebbling strategy that requires  $2^{O(d)}$  steps and each configuration can be described by  $d \cdot \log s$  bits.

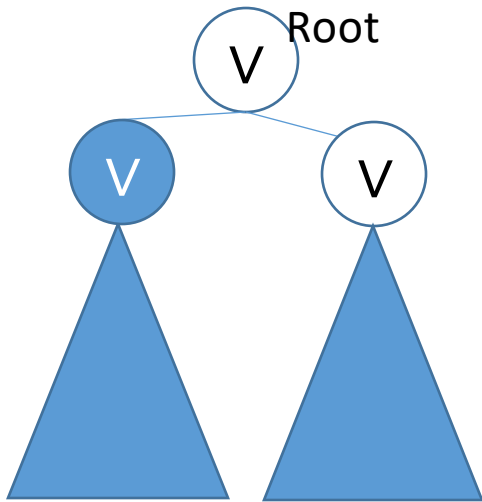

Recursively pebble the left child of the root.  
Add (RootGate,0) to configuration

# Proof of Adaptive Security

We give a pebbling strategy that requires  $2^{O(d)}$  steps and each configuration can be described by  $d \cdot \log s$  bits.

Recursively pebble the left child of the root.  
Add (RootGate,0) to configuration

# Proof of Adaptive Security

We give a pebbling strategy that requires  $2^{O(d)}$  steps and each configuration can be described by  $d \cdot \log s$  bits.

Recursively pebble the right child of the root.  
Update (RootGate,1) in configuration

# Proof of Adaptive Security

We give a pebbling strategy that requires  $2^{O(d)}$  steps and each configuration can be described by  $d \cdot \log s$  bits.

Recursively pebble the right child of the root.  
Update (RootGate,1) in configuration

# Proof of Adaptive Security

We give a pebbling strategy that requires  $2^{O(d)}$  steps and each configuration can be described by  $d \cdot \log s$  bits.

Put a pebble on the root  
Update Bit in configuration

# Proof of Adaptive Security

We give a pebbling strategy that requires  $2^{O(d)}$  steps and each configuration can be described by  $d \cdot \log s$  bits.

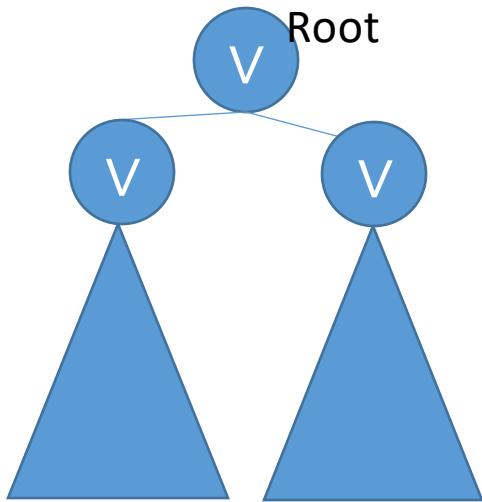

Put a pebble on the root  
Update Bit in configuration

# Proof of Adaptive Security

We give a pebbling strategy that requires  $2^{O(d)}$  steps and each configuration can be described by  $d \cdot \log s$  bits.

Unpabble right subtree of root  
Update (RootGate,1) in configuration

# Proof of Adaptive Security

We give a pebbling strategy that requires  $2^{O(d)}$  steps and each configuration can be described by  $d \cdot \log s$  bits.

Unpabble right subtree of root  
Update (RootGate,1) in configuration

# Proof of Adaptive Security

We give a pebbling strategy that requires  $2^{O(d)}$  steps and each configuration can be described by  $d \cdot \log s$  bits.

Unpabble left subtree of root  
Remove (RootGate,1) from configuration

# Proof of Adaptive Security

We give a pebbling strategy that requires  $2^{O(d)}$  steps and each configuration can be described by  $d \cdot \log s$  bits.

Unpabble left subtree of root  
Remove (RootGate,1) from configuration

$T(d) = \#$  of pebbling rules

$$T(d) = 2 \cdot 2 \cdot T(d - 1)$$

$L(d) = \text{size of conf.}$

$$L(d) = L(d - 1) + \log s + 2$$

# Conclusions

Thank You!

- A new framework for proving adaptive security
  - Simplified proof of adaptive security:  
GSD, Constrained PRFs, Yao's Garbled circuits
  - New result for Yao's secret sharing scheme.
- Find more applications where this framework applies
- Find better pebbling strategies
- Is there a connection in the other direction between pebbling strategies and the security loss?
  - Can we use lower bounds for pebbling strategies to devise attacks?
